1                    COMPOSING A REALIGNED IMAGE

2            PRIORITY

3            The present application claims priority of Provisional  
4            Application, Application Number 60/117,866, having the  
5            same title and a filing date of 01/29/99, by inventors  
6            Gordon Braudaway et al.

7            CROSS REFERENCES

8            The present application is related to the following  
9            applications even dated with the above referenced  
10           Provisional Application: Application Number 09/240,242,  
11           entitled, "Recovering Invisible Digital Image  
12           Watermarks From Distorted Images," by inventors Gordon  
13           Braudaway et al.; and Application Number 60/117,921  
14           entitled, "Watermarking and Determining Distortion in  
15           an Image," by inventors Gordon Braudaway et al., which  
16           are incorporated herein by reference in their entirety.

1     FIELD OF THE INVENTION

2     This application relates to the field of digitized  
3     imaging. It is more specifically directed to  
4     determining and removal of image distortion from an  
5     image.

6     BACKGROUND OF THE INVENTION

7     With the development of means of production and  
8     circulation of digital images, and the means of  
9     imbedding relatively invisible watermarks into digital  
10    images ostensibly to convey ownership of the image,  
11    there is now financial incentive to attack an imbedded  
12    watermark in an attempt to render it non-extractable.  
13    Pixel locations of a watermarked image are presumed to  
14    correspond to those in an unmarked original image.  
15    Generally, the watermark is imbedded by altering only  
16    the values of the pixel components of the original  
17    image, not their geometric positions. This may be  
18    accomplished employing such methods as described in US  
19    Patent 5,825,892 which is incorporated herein by  
20    reference in its entirety.

21    Some methods of attacking an imbedded watermark rely on  
22    constructing a new image that is a geometrically

1 distorted copy of the watermarked image. This new  
2 image is herein referred to as a **distorted copy**.  
3 Pixels in the distorted copy are placed at subtly  
4 distorted positions relative to those in the  
5 watermarked image. Pixel component values in the  
6 distorted copy are determined by two-dimensional  
7 interpolation of component values of enclosing pixel in  
8 the watermarked image. No constraints can be placed on  
9 the types of pixel position distortion an attacker  
10 might choose to use. To those skilled in the art,  
11 however, it is obvious that excessive pixel  
12 position-distortion will cause the distorted copy to be  
13 a caricature of the watermarked image, thus diminishing  
14 or destroying its economic value. Whether a distortion  
15 is excessive is a subjective measure. For a distorted  
16 copy to be useful, it requires that linear or nonlinear  
17 distortion methods that are used by an attacker have to  
18 be used sparingly and in such a manner as to produce  
19 smoothly varying and relatively small position  
20 distortions. This is so as to be essentially  
21 unobjectionable and casually unnoticeable to untrained  
22 observers. The human visual system, as a qualitative  
23 measuring device, can be relied upon to readily detect  
24 excessive distortion. It is desirable to have a method  
25 of defense that requires little or no limits to be  
26 placed on pixel position-distortions produced by the  
27 attacking method.

1        SUMMARY OF THE INVENTION

2        In one aspect, the present invention provides a method,  
3        apparatus and article of manufacture employing an  
4        undistorted reference image relative to which  
5        measurements of distortion are made. These employ an  
6        automatic method for composing a **realigned** image which  
7        does not depend on a process of visually examining a  
8        **composite image**, and recording the coordinates of pixel  
9        locations closest to common image features in a  
10       **distorted image** and **reference image**. If the presumed  
11       **distorted image** is not the same size as the **reference**  
12       **image**, it is made so by shrinking or enlarging the  
13       **reference image**. At the next step, at least three  
14       distinct points that do not form a straight line are  
15       selected. The integer coordinates of the pixels  
16       nearest these points are herein referred to as  
17       **reference centers**. At each reference center, a segment  
18       of each image, herein referred to as a sub-image, is  
19       excised, thus producing for each image as many  
20       sub-images as there are distinct points. The  
21       horizontal and vertical dimensions of the sub-images,  
22       in integer pixel coordinates, are respectively based on  
23       the common horizontal and vertical dimensions of the  
24       images. A pair of sub-image, one excised from the  
25       **reference image** and the other excised from the  
26       **distorted image**, having the same reference center are  
27       manipulated to determine and/or substantially remove  
28       the distortion from the distorted image.

Another aspect of the present invention enables a digital image watermark to be extracted from a geometrically distorted copy of a reference image.

Other aspects and a better understanding of the invention may be realized by referring to the Detailed Description.

#### BRIEF DESCRIPTION OF THE DRAWING

These and other objects, features, and advantages of the present invention will become apparent upon further consideration of the following detailed description of the invention when read in conjunction with the drawing figure.

#### DESCRIPTION OF THE INVENTION

The present invention provides a method, apparatus and article of manufacture by which the distortion in a distorted copy of an image is automatically measured and removed sufficiently well that a relatively invisible image watermark extraction is possible. In an embodiment of the invention, the method employs a **reference image** relative to which measurements of distortion are made. For example, an original unmarked image or a relatively invisibly watermarked copy of the

1 locations are the **reference centers**. At each reference  
2 center, a segment of each image, herein referred to as  
3 a sub-image, is excised, thus producing for each image  
4 as many sub-images as there are common pixel locations.  
5 The horizontal and vertical dimensions of the  
6 sub-images, in integer pixel coordinates, are based on  
7 the common horizontal and vertical dimensions,  
8 respectively, of the images. The pair of sub-images,  
9 one excised from the **reference image** and the other  
10 excised from the **geometric alteration**, having the same  
11 reference center are herein referred to as  
12 **corresponding sub-images**. A typical embodiment employs  
13 three common pixel locations.

14 When the geometric alteration is laid upon the  
15 reference image, the intersection of pixels in the  
16 reference image with pixels in the geometric alteration  
17 is an area of each image called the **safe area**.  
18 Although initially the safe area is the entire area of  
19 the geometric alteration and the reference image, on  
20 subsequent iterations of this realignment method the  
21 safe area may be smaller than the reference image.  
22 Each sub-image is centered at its respective reference  
23 center. If any pixel of a sub-image extends beyond the  
24 boundaries of the safe area, such as at the edges of  
25 the safe area, then the top or bottom edge of the  
26 corresponding sub-images, and the left or right edge of  
27 the corresponding sub-images, if also necessary, are  
28 repositioned. The two subimages, in unison, are  
29 repositioned vertically and horizontally by the minimum

number of pixel locations necessary so that no pixel of either sub-image lies in whole or in part outside of the safe area. The corresponding reference center is adjusted to lie at the center of the repositioned sub-images. Reference centers, after this adjustment process, are referred to as **adjusted centers**, whether they were adjusted or not. Note that in the case where the sub-image horizontal width,  $I$ , and vertical height,  $J$ , are even integers, such as powers of two, and the coordinates of the sub-images are indexed 0 to  $I-1$  and 0 to  $J-1$ , respectively, the integer coordinates of the center of each sub-image are defined to be  $I/2$  and  $J/2$ . Also note that  $I$  should be less than the width and  $J$  should be less than the height of the reference image and the geometric alteration.

The  $n$ -th pair of sub-images, one from the reference image designated the  $n$ -th reference sub-image and a corresponding one from the geometric alteration designated the  $n$ -th distorted sub-image, is used to compute a two-dimensional cross-correlation surface relating the distorted sub-image with the reference sub-image image. Those skilled in the art will recognize that there are many methods that may be used to compute or approximate a cross-correlation surface relating the two corresponding sub-images. Regardless of the method used, any method that produces the intended result of determining the horizontal and vertical offsets of the distorted sub-image relative to the reference sub-image that achieves a good match may

1 be employed. For example, a good match has offsets  
2 that can not be improved by more than the spacing of  
3 1.5 pixels in any direction by using any other means of  
4 pattern matching. A better match is readily achievable  
5 if the distortions are generally linear. Watermark  
6 detection seldom requires a match better than a 0.5-2.0  
7 pixel spacing. If required, more complex iteration  
8 techniques may be used to achieve a best match.

9 In an example embodiment, forward and inverse discrete  
10 Fast Fourier Transforms (FFT's) are used to compute a  
11 cross-correlation surface. Note that for methods using  
12 FFT's, all sub-images are converted to monochrome, if  
13 not already so. The non-integer interpolated  
14 horizontal and vertical offsets of the peak of the  
15 cross-correlation surface,  $p_n$  and  $q_n$ , relative to the  
16 origin of the cross-correlation surface are used as  
17 additive offsets relating the center of the  $n$ -th  
18 distorted sub-image relative to the  $n$ -th corresponding  
19 adjusted center. Thus, for each pair of sub-images,  
20 the coordinates of the adjusted center are the center  
21 on the  $n$ -th reference sub-image. The sums of the  
22 coordinates of the adjusted center plus the offsets of  
23 the peak of the  $n$ -th cross-correlation surface become  
24 the approximate coordinates of the center of the  
25 distorted sub image,  $u_n = x_n + p_n$  and  $v_n = y_n + q_n$ . The  
26 coordinates of the offset center of the distorted  
27 sub-sub image and the adjusted center, herein referred  
28 to as computed pixel coordinates, are analogous to the  
29 measured pixel coordinates of common features visually

1 selected from the geometric alteration and reference  
2 image of the previously cited semiautomatic method.  
3 Using the computed pixel coordinates instead of the  
4 measured pixel coordinates, the coefficients matrix, **A**,  
5 of the pixel position interpolation equations are  
6 computed, as in the semiautomatic method.

7 In another example embodiment, forward and inverse  
8 discrete Fast Fourier Transforms (FFT's) are used to  
9 compute a modified cross-correlation surface. The  
10 magnitudes of the Fourier transform coefficients are  
11 modified to make said magnitudes uniform. An inverse  
12 Fourier transform is used to compute the modified  
13 cross-correlation surface.

14 In yet another example embodiment, a weighted sum of  
15 the ordinary and modified Fourier transform  
16 coefficients is formed before using an inverse Fourier  
17 transform to compute a weighted cross correlation  
18 surface.

19 In an embodiment of the automatic method, use of a  
20 statistical screen is incorporated into the next step.  
21 Use of a statistical screen is generally not needed in  
22 the semiautomatic method. Because the selection of  
23 sub-images is done indiscriminately, it is possible  
24 that some sub-images may have few features (or even  
25 none). The cross-correlation surfaces computed from  
26 such sub-images may be relatively flat and have a  
27 misleading peak. An additional test is used to

1 discriminate against statistical out-flyers that can  
2 occur from such misleading peaks. As used herein, an  
3 'out-flyer' is a value from a set of values that  
4 deviates so greatly from the other values in the set  
5 that it is statistically unlikely to be a member of the  
6 set.

7 An example statistical screen discriminating against  
8 out-flyers is embodied as follows. Each of the pairs  
9 of computed pixel coordinates,  $u_n$  and  $v_n$ , is processed  
10 by the interpolation equations to give a **proposed**  
11 **reference center**,  $x_n'$  and  $y_n'$ . The Euclidean distance  
12 between the proposed reference center and the  
13 corresponding adjusted center,  $x_n$  and  $y_n$ , is computed  
14 for each of the  $n$  sub-images. Out-flyers are deleted  
15 from the set of  $n$  Euclidean distances, largest first,  
16 based on their value being above a first threshold  
17 value. If any out-flyer is deleted, the offset center  
18 of its corresponding distorted sub-image and adjusted  
19 center are also deleted. The coefficients, **A**, are  
20 recomputed using the undeleted pairs of pixel  
21 coordinated, but never with fewer than three pairs of  
22 pixel coordinates.

23 From this point on, the automatic and semiautomatic  
24 methods generally parallel one another. The square  
25 submatrix,  $S_A$ , of four of the coefficients of the  
26 interpolation equations is factored into four primitive  
27 image manipulation matrices. The **geometric alteration**

1 is manipulated by the four primitive image  
2 manipulations to form the **reoriented image**.

3 The entire restoration process is advantageously  
4 repeated iteratively by substituting the previously  
5 reoriented image for the geometric alteration before  
6 each subsequent iteration. For the automatic method,  
7 it has been found that for images with significant  
8 distortion, as many as three iterations are warranted.  
9 For attacks with more nonlinear distortion, additional  
10 iterations may be used to further improve reorientation  
11 of the **geometric alteration**. The iteration process is  
12 terminated when examination of the Euclidean distances  
13 shows that the reduction of all Euclidean distances  
14 relative to those from the previous iteration is less  
15 than a second threshold. Finally, the **reoriented image**  
16 is realigned left or right and up or down relative to  
17 the **reference image**, based on the offset coefficients **c**  
18 and **f** from the interpolation equations, to form the  
19 **realigned image**.

20 An overview of the steps of an example automatic  
21 realignment of a presumed distorted copy is shown in  
22 the figure. First, if the presumed **distorted copy** is  
23 not the same size as the **reference image**, it is shrunk  
24 or enlarged to make it the same size using any image  
25 resizing method; the resized **distorted copy** is herein  
26 referred to as the **geometric alteration**, (102).

1 In a particular embodiment, a common coarse but  
2 regularly spaced mesh having  $n$  knots is superimposed on  
3 both of the images, (104). The knots of the mesh serve  
4 as reference points for each of the images. A list of  
5 the horizontal and vertical coordinates,  $x_n$  and  $y_n$ , of  
6 pixels lying closest to the knots of the mesh is built;  
7 these coordinate pairs are herein referred to as the  
8 **reference centers**, (106). A **sub-image**, having  
9 dimensions  $I$  and  $J$  and centered at each of the  
10 **reference centers**, is excised from each of the images  
11 and converted to monochrome, if not already so, (108),  
12 producing  $n$  corresponding pairs of sub images. A safe  
13 area is determined as the intersection of pixels common  
14 to the geometric alteration and reference image (110).  
15 If any part of any **sub-image** lies beyond the boundaries  
16 of the safe area, it is repositioned left or right and  
17 up or down a minimum number of pixel locations until  
18 both it and its **corresponding sub-image** lie within the  
19 boundaries of the safe area, and their common reference  
20 center is adjusted to again lie at the center of the  
21 repositioned sub-images, (112). A two-dimensional  
22 cross correlation surface is computed from each of the  
23  $n$  pairs of sub-images, (114). The non-integer  
24 horizontal and vertical **coordinate offsets**,  $p_n$  and  $q_n$ ,  
25 of the greatest peak on each of the  $n$  cross-correlation  
26 surfaces are determined by two-dimensional  
27 interpolation, (116). The **distorted reference centers**  
28 are computed by adding the **coordinate offsets** to their  
29 corresponding **adjusted centers**, (118). Using the  
30 **adjusted centers** and the **distorted reference centers** in

1     stead of the manually measured pixel coordinate pairs,  
2     as in the referenced semiautomatic method, the  
3     coefficients matrix, **A**, of the pixel position  
4     interpolation equations is computed, (120), in a manner  
5     identical to that used in the cross-referenced  
6     semiautomatic method.

7     In this embodiment, the automatic method differs from  
8     the cross-referenced semiautomatic method in at least  
9     the next steps. Using the pixel position interpolation  
10    equations, each of the **distorted reference centers** is  
11    converted to form a **proposed reference center**. The  
12    Euclidean distance between each of the **proposed**  
13    **reference center** and its corresponding **adjusted center**  
14    is computed. Those that are "out-flyers", for example  
15    those greater than a first threshold, say a spacing of  
16    5 pixels, are discarded while at least three are always  
17    retained, (122). If any of the **distorted reference**  
18    **centers** is discarded, (124), steps (120) through (124)  
19    are repeated using only the not-discarded adjusted  
20    centers and the not-discarded distorted reference  
21    centers. Otherwise, as in the referenced semiautomatic  
22    method, the square submatrix, **S<sub>A</sub>**, of four of the  
23    coefficients is factored into four primitive image  
24    manipulating matrices, (126), and the **geometric**  
25    **alteration** is manipulated by the four primitive image  
26    manipulations to form the **reoriented image**, (128).

27    If any of the primitive manipulations is not  
28    sufficiently small, as determined by comparing the

1        **CLAIMS:**

2        Having thus described our invention, what we claim as  
3        new and desire to secure by Letters Patent is as  
4        follows:

5        1. A method for restoring a geometrically distorted  
6        copy of a reference image, said method comprising:

7        automatically determining a type and amount of  
8        distortion of said distorted copy; and

9        substantially reversing the distortion to form a  
10       reoriented image.

11       2. A method as recited in claim 1, further comprising  
12       horizontally and vertically aligning the reoriented  
13       image with the reference image to form a realigned  
14       image.

15       3. A method as recited in claim 2, further comprising  
16       extracting a watermark from the realigned image.

17       4. A method as recited in claim 1, wherein the step of  
18       automatically determining includes:

19       composing a geometric alteration of the distorted copy  
20       by making the distorted copy the same size as the  
21       reference image;

discarding said each distorted center and its  
corresponding adjusted center that define a Euclidean  
distance that is statistically improbable while  
retaining at least three not-discarded distorted  
centers and their corresponding adjusted centers; and

recomputing the coefficients matrix, **A**, of a pixel  
position interpolation equation using the at least  
three not-discarded distorted centers and corresponding  
adjusted centers.

6. A method as recited in claim 4, wherein the steps  
of substantially reversing includes:

factoring the sub-matrix  $S_A$  into four primitive image  
manipulation matrices;

applying the four primitive image manipulation matrices  
to the geometric alteration to produce a reoriented  
image;

making the geometric alteration identical to the  
reoriented image if any primitive image manipulation  
matrix produces a distortion greater than a  
predetermined threshold, said distortion determined by  
examining all iteration-to-iteration incremental  
changes in the Euclidean distances; and

repeating all the steps of claim 4 except the step of  
composing, all the steps of claim 5, and the steps of

1 factoring, applying and making until no primitive image  
2 manipulation matrix produces a distortion greater than  
3 the predetermined threshold.

4 7. A method, as recited in claim 4, wherein the step  
5 of horizontally and vertically aligning includes  
6 translating horizontally the reoriented image by the  
7 value of the third coefficient of the matrix, A, and  
8 translating vertically the reoriented image by the  
9 value of the sixth coefficient of the matrix, A, to  
10 form the realigned image.

11 8. A method as recited in claim 3, wherein the step of  
12 composing includes:

13 shrinking or enlarging the distorted copy vertically by  
14 pixel interpolation or extrapolation such that the  
15 produced geometric alteration has a same height as the  
16 reference image, and

17 shrinking or enlarging the produced geometric  
18 alteration horizontally by pixel interpolation or  
19 extrapolation to have the same width as the reference  
20 image.

21 9. A method as recited in claim 4, wherein the  
22 coordinate offsets are non-integers and the step of  
23 locating includes using interpolation.

1 10. A method, as recited in claim 1, wherein the  
2 reference image is an original unmarked image.

3 11. A method as recited in claim 4, wherein the step  
4 of computing includes:

5 comparing a region in the geometric alteration  
6 surrounding each of said reference centers with regions  
7 in the reference image shifted in position by a  
8 multiplicity of coordinate offsets;

9 ascertaining horizontal and vertical coordinate offsets  
10 of each selected reference center as being the  
11 horizontal and vertical offset at which the region in  
12 the geometric alteration and the region on the  
13 reference image most nearly match; and

14 calculating the distorted centers from the coordinate  
15 offsets and the corresponding reference centers.

16 12. A method as recited in claim 11, wherein the step  
17 of comparing includes:

18 using a modified cross correlation function in which  
19 the Fourier transform of the cross correlation function  
20 is computed, wherein magnitudes of the Fourier  
21 transform coefficients are modified to make said  
22 magnitudes uniform, and

1 using an inverse Fourier transform to compute the  
2 modified correlation function.

3 13. A method as recited in claim 11, wherein the step  
4 of comparing includes:

5 using a weighted cross correlation function in which  
6 the Fourier transform of the cross correlation function  
7 is computed, wherein a weighted sum of the ordinary and  
8 modified Fourier transform coefficients is formed, and

9 using an inverse Fourier transform to compute the  
10 weighted correlation function.

11 14. A method as recited in claim 8, wherein the step  
12 of ascertaining includes:

13 composing a geometric alteration of the distorted copy  
14 by making the distorted copy the same size as the  
15 reference image;

16 defining a safe area having safe pixels, wherein said  
17 safe area is an intersection of pixels in the reference  
18 image with pixels in the geometric alteration, and said  
19 safe pixels includes any pixel from the reference image  
20 or the geometric alteration which lies in the safe  
21 area;

22 building a list of reference centers, wherein each  
23 reference center corresponds to coordinates of a

1 particular pixel in the safe area lying closest to a  
2 particular one of said at least three pixel locations;

3 computing a plurality of corresponding distorted  
4 centers;

5 using the reference centers and the corresponding  
6 distorted centers to compute coefficients of a matrix,  
7 A, of pixel position interpolation equations;

8 testing each distorted center to determine if said each  
9 distorted center is statistically improbable; and

10 discarding each distorted center that is statistically  
11 improbable while retaining at least three not-discarded  
12 distorted centers, until no more distorted centers are  
13 discarded.

14 15. An article of manufacture comprising a computer  
15 usable medium having computer readable program code  
16 means embodied therein for causing a restoring of a  
17 geometrically distorted copy of a reference image, the  
18 computer readable program code means in said article of  
19 manufacture comprising computer readable program code  
20 means for causing a computer to effect:

21 automatically determining a type and amount of  
22 distortion of said distorted copy; and

1 regions in the reference image shifted in position by a  
2 multiplicity of coordinate offsets;

3 ascertaining horizontal and vertical coordinate offsets  
4 of each selected reference centers as being the  
5 horizontal and vertical offset at which the region in  
6 the geometric alteration and the region on the  
7 reference image most nearly match; and

8 determining the type and amount of distortion from the  
9 coordinate offsets and the set of reference centers.

10 20. An article of manufacture as recited in claim 19,  
11 wherein the step of comparing includes:

12 using a modified correlation function in which the  
13 Fourier transform of the correlation function is  
14 computed, wherein the magnitudes of the Fourier  
15 transform coefficients are modified to make said  
16 magnitudes uniform, and

17 using an inverse Fourier transform to compute the  
18 modified correlation function.

19 21. An article of manufacture as recited in claim 19,  
20 wherein the step of ascertaining includes performing a  
21 least-squares fit on the horizontal and vertical  
22 coordinate offsets of the set of reference centers.

1 22. A computer program product comprising a computer  
2 usable medium having computer readable program code  
3 means embodied therein for causing a readjusting of a  
4 geometrically distorted copy of a reference image, the  
5 computer readable program code means in said computer  
6 program product comprising computer readable program  
7 code means for causing a computer to effect:

8 automatically determining a type and amount of  
9 distortion of said distorted copy; and

10 substantially reversing the distortion to form a  
11 reoriented image.

12 23. An apparatus for restoring a geometrically  
13 distorted copy of a reference image, said method  
14 comprising:

15 means for automatically determining a type and amount  
16 of distortion of said distorted copy; and

17 means for substantially reversing the distortion to  
18 form a reoriented image.

19 24. An apparatus as recited in claim 23, further  
20 comprising horizontally and vertically aligning the  
21 reoriented image with the reference image to form a  
22 realigned image.

1 25. An apparatus as recited in claim 24, further  
2 comprising means for extracting a watermark from the  
3 realigned image.

4 26. An apparatus as recited in claim 23, wherein the  
5 means for automatically determining includes:

6 means for composing a geometric alteration of the  
7 distorted copy by making the distorted copy the same  
8 size as the reference image;

9 means for defining a safe area having safe pixels,  
10 wherein said safe area is an intersection of pixels in  
11 the reference image with pixels in the geometric  
12 alteration, and said safe pixels includes any pixel  
13 from the reference image or the geometric alteration  
14 which lies in the safe area;

15 means for selecting 'n' points in the safe area,  
16 wherein 'n' is at least three and not all 'n' points  
17 lie on a straight line;

18 means for building a list of 'n' reference centers,  
19 wherein each reference center corresponds to  
20 coordinates of a particular pixel lying closest to a  
21 particular one of said 'n' points;

22 means for constituting a plurality of pairs of  
23 sub-images, wherein each pair is centered at one of  
24 said reference centers and each pair is formed by a

1 sub-image from the geometric alteration and a  
2 corresponding sub-image from the reference image;

3 means for minimally horizontally and vertically  
4 positioning from an original sub-image position to a  
5 new sub-image position any sub-image pair having any  
6 sub-image pixel lying outside the safe area, such that  
7 said any sub-image pixel lies within the safe area;

8 means for adjusting the reference center of said any  
9 sub-image pair to correspond to said new sub-image  
10 position;

11 means for computing a two-dimensional cross correlation  
12 surface from each of the 'n' pairs;

13 means for locating a horizontal,  $p_n$ , and a vertical,  
14  $q_n$ , coordinate offset of the greatest peak on each  
15 cross-correlation surface;

16 means for calculating a plurality of distorted centers;

17 means for using the adjusted centers and the  
18 corresponding distorted centers to compute the  
19 coefficients matrix, A, of a pixel position  
20 interpolation equation; and

21 means for forming a sub-matrix,  $S_A$ , from the first,  
22 second, fourth and fifth elements of the matrix A.

1 27. An apparatus as recited in claim 26, further  
2 comprising:

3 means for computing a set of proposed reference centers  
4 based on the distorted reference centers and the pixel  
5 position interpolation equations;

6 means for computing the Euclidean distances between the  
7 proposed reference centers and the adjusted centers;

8 means for testing each Euclidean distances to determine  
9 if said each Euclidean distance is statistically  
10 improbable;

11 means for discarding said each distorted center and its  
12 corresponding adjusted center that define a Euclidean  
13 distance that is statistically improbable while  
14 retaining at least three not-discarded distorted  
15 centers and their corresponding adjusted centers; and

16 means for recomputing the coefficients matrix, **A**, of a  
17 pixel position interpolation equation using the at  
18 least three not-discarded distorted centers and  
19 corresponding adjusted centers.

20 28. An apparatus as recited in claim 26, wherein the  
21 coordinate offsets are non-integers, and the means for  
22 locating includes using interpolation.

29. A method as recited in claim 1, wherein the steps of automatically determining and substantially reversing are repeatedly applied until an amount of the distortion falls below a given threshold.

30. A method as recited in claim 29, wherein the given threshold is less than a 0.5 pixel spacing.

31. A method comprising:

automatically measuring the degree of distortion imparted upon a distorted replica of an original image;

substantially reversing the degree of distortion of the distorted replica to form an undistorted image; and

aligning the undistorted image with the original image.

32. A method as recited in claim 31, further comprising determining whether the distorted replica image has been geometrically distorted relative to another form of the original image.

33. An article of manufacture comprising a computer usable medium having computer readable program code means embodied therein for causing restoration of an image, the computer readable program code means in said

1 article of manufacture comprising computer readable  
2 program code means for causing a computer to effect:

3 automatically measuring the degree of  
4 distortion imparted upon a distorted replica  
5 of an original image;

6 substantially reversing the degree of  
7 distortion of the distorted replica to form  
8 an undistorted image; and

9 aligning the undistorted image with the  
10 original image.

11 34. An article of manufacture as recited in claim 32,  
12 the computer readable program code means in said  
13 article of manufacture further comprising computer  
14 readable program code means for causing a computer to  
15 effect determining whether the distorted replica image  
16 has been geometrically distorted relative to another  
17 form of the original image.

18 35. A method as recited in claim 4, wherein the step  
19 of selecting 'n' points includes employing a simulated  
20 mesh with knots.

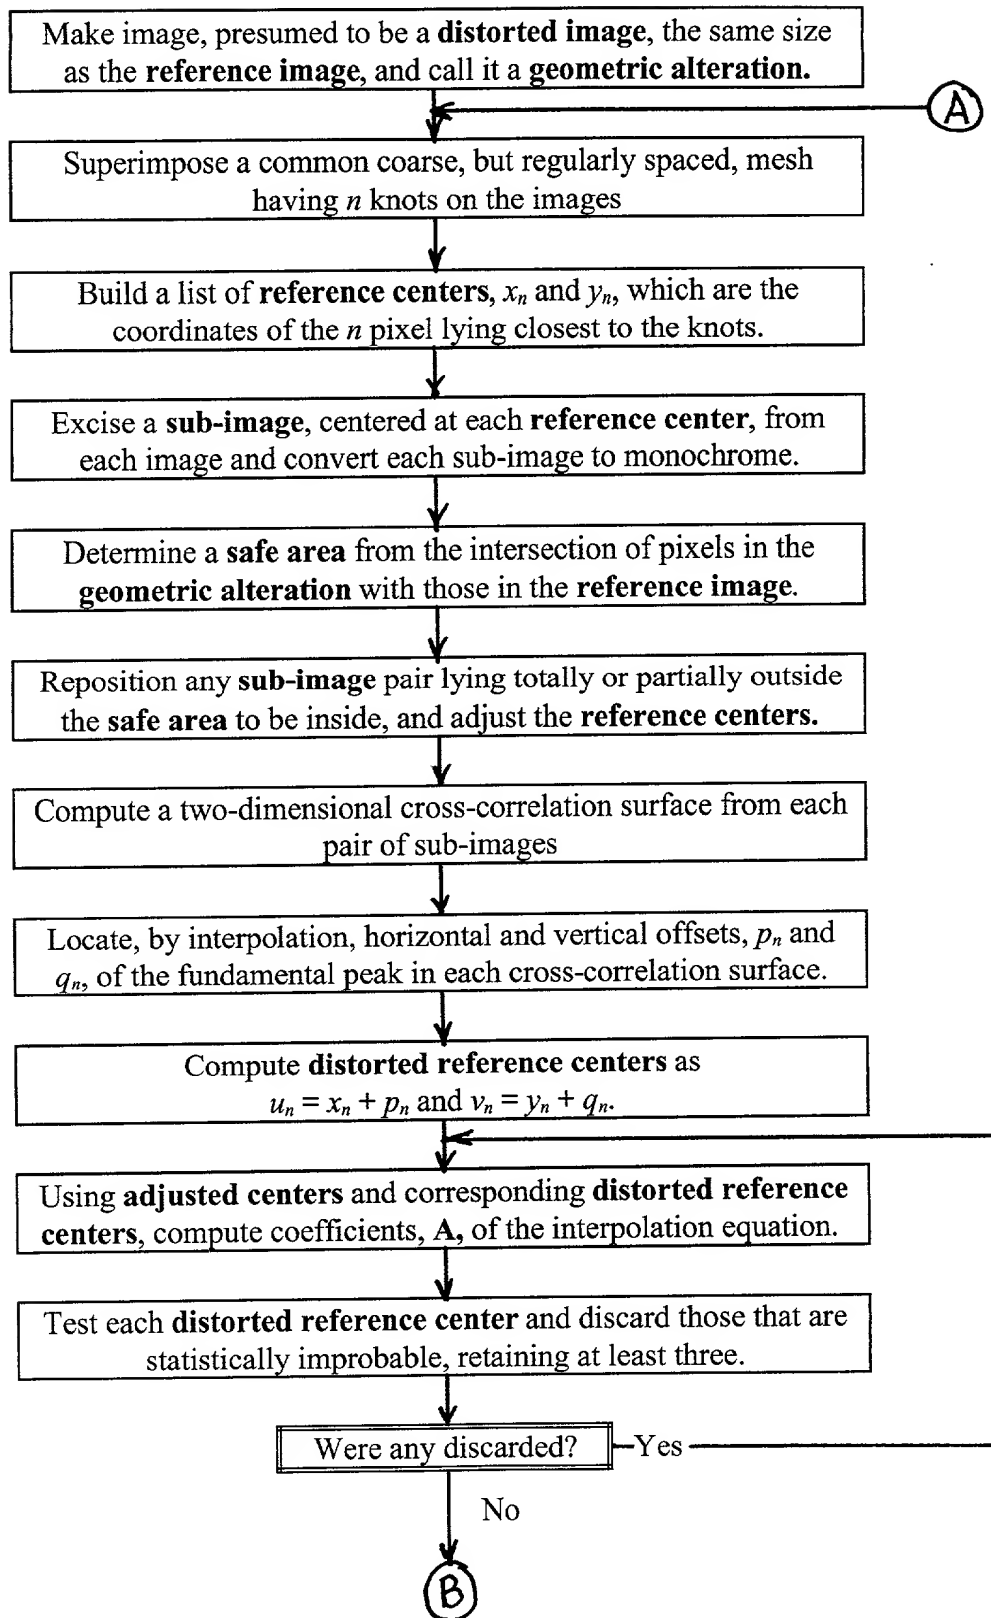

1                    COMPOSING A REALIGNED IMAGE

2                    ABSTRACT OF THE INVENTION

3        This invention provides methods, apparatus and article  
4        of manufacture used as a countermeasure to image  
5        distorting. The present invention involves  
6        automatically detecting the presence of distortion in a  
7        presumed distorted image, measuring the magnitude and  
8        type of distortion, and finally creating a realigned  
9        image. Once image distortion is removed, conventional  
10       invisible watermark extraction methods are employed to  
11       extract the watermark from the realigned image. The  
12       automatic method does not depend on a process of  
13       visually examining a composite image and recording the  
14       coordinates of pixel locations closest to common image  
15       features in a distorted image and reference image.  
16       Generally, the presumed distorted image is resized to  
17       the same size as the reference image. Reference  
18       centers at at least three distinct points that do not  
19       form a straight line are selected. At each reference  
20       center, a sub-image is excised. Pairs of sub-images,  
21       one excised from the reference image and the other  
22       excised from the distorted image, having the same  
23       reference center are used in the process of removal of  
24       the distortion.

**DECLARATION AND POWER OF ATTORNEY FOR PATENT APPLICATION**

As a below named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name;

I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled:

COMPOSING A REALIGNED IMAGE

the specification of which (check one)

☒ is attached hereto.

\_\_\_\_\_ was filed on \_\_\_\_\_ as United States Application Number

or PCT International Application Number \_\_\_\_\_

and was amended on \_\_\_\_\_ (if applicable)

I hereby state that I have reviewed and understand the contents of the above identified specification, including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose information which is material to the patentability of this application in accordance with Title 37, Code of Federal Regulations, Section 1.56.

I hereby claim foreign priority benefits under Title 35, United States Code, '119(a)-(d) or '365(b) of any foreign application(s) for patent or inventor's certificate, or '365(a) of any PCT International application which designated at least one country other than the United States, listed below and have also identified below, by checking the box, any foreign application for patent or inventor's certificate, or PCT International application, having a filing date before that of the application on which priority is claimed:

Prior Foreign Application(s)			Priority Claimed	
(Number)	(Country)	(Day/Month/Year Filed)	<input type="checkbox"/> Yes	<input type="checkbox"/> No
(Number)	(Country)	(Day/Month/Year Filed)	<input type="checkbox"/> Yes	<input type="checkbox"/> No
(Number)	(Country)	(Day/Month/Year Filed)	<input type="checkbox"/> Yes	<input type="checkbox"/> No

I hereby claim the benefit under 35 U.S.C. '119(e) of any United States provisional application(s) listed below.

60/117,866	January 29, 1999
(Application Number)	(Filing Date)
(Application Number)	(Filing Date)

I hereby claim the benefit under 35 U.S.C. '120 of any United States Application(s), or '365(c) of any PCT International application designating the United States, listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States, or PCT International application in the manner provided by the first paragraph of 35 U.S.C. '112, I acknowledge the duty to disclose information material to the patentability of this application as defined in 37 CFR '1.56 which occurred between the filing date of the prior application and the national or PCT international filing date of this application:

(Application Serial No.)	(Filing Date)	(Status) (patented, pending, abandoned)
(Application Serial No.)	(Filing Date)	(Status) (patented, pending, abandoned)

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that willful false statements may jeopardize the validity of the application or any patent issued thereon.

POWER OF ATTORNEY: As a named inventor I hereby appoint the following attorney(s) and/or agent(s) to prosecute this application and transact all business in the Patent and Trademark Office connected therewith (list name and registration number).

Manny W. Schecter (Reg. 31,722), Terry J. Ilardi (Reg. 29,936), Christopher A. Hughes (Reg. 26,914), Edward A. Pennington (Reg. 32,588), John E. Hoel (Reg. 26,279), Joseph C. Redmond, Jr. (Reg. 18,753), Douglas W. Cameron (Reg. 31,596), Louis P. Herzberg (Reg. 41,500), Kevin M. Jordan (Reg. 40,277), Stephen C. Kaufman (Reg. 29,551), Daniel P. Morris (Reg. 32,053), Louis J. Percello (Reg. 33,206), Jay P. Sbrollini (Reg. 36,266), David M. Shofi (Reg. 39,835), Robert M. Trepp (Reg. 25,933) and Paul J. Otterstedt (Reg. 37,411).
